## ABSTRACT

Primary Examiner — David Nhu  
(74) Attorney, Agent, or Firm — Sherry W. Schumm

Embodiments of methods for forming a semiconductor device that includes a die and a substrate include pressing together the die and the substrate such that a first gold layer and one or more additional material layers are between the die and the substrate, and performing a bonding operation to form a die attach layer between the die and the substrate. The die attach layer includes a gold interface layer that includes gold and a plurality of first precipitates in the gold. Each of the first precipitates includes a combination of nickel, cobalt, palladium, gold, and silicon.

## METHODS FOR BONDING A DIE AND A SUBSTRATE

### CROSS-REFERENCE TO RELATED APPLICATION

This application is a continuation of U.S. patent application Ser. No. 12/683,961, filed on Jan. 7, 2010, and now issued at U.S. Pat. No. 8,753,983 B2.

### BACKGROUND

#### 1. Field

This disclosure relates generally to semiconductor device packaging, and more specifically, to die bonding used in semiconductor device packaging.

#### 2. Related Art

The functionality of semiconductor devices continues to provide very significant utility. Because of the very small size of the die that makes a semiconductor device, the interface with the system of which it is a part is very important. Also the ability to dissipate heat can be very significant. Generally, the die is attached to something rigid that is useful in providing an interface with a system and also may be useful in dissipating heat. In one type of case the die is bonded to a substrate which is useful for physical support and as a heat sink for heat dissipation. An effective way this is done is to bond the metal to the die through a gold/silicon (AuSi) eutectic bond. The back of the die is coated with gold. The substrate may have a first coating that functions as a barrier and a second coating of gold on the first coating. A common composition for the barrier is cobalt and nickel. The gold layers are pressed together and heated to form a eutectic bond to provide physical attachment and for conducting heat. This may provide the desired functions but the gold is quite expensive. Cost continues to be important so there is a need for a lower cost die bond.

### BRIEF DESCRIPTION OF THE DRAWINGS

The present invention is illustrated by way of example and is not limited by the accompanying figures, in which like references indicate similar elements. Elements in the figures are illustrated for simplicity and clarity and have not necessarily been drawn to scale.

FIG. 1 is a cross section of a heat sink and a die prior to being attached according to an embodiment;

FIG. 2 is a cross section of the heat sink and die of FIG. 1 after being attached;

FIG. 3 is a more detailed view, in cross section, of an interface between the heat sink and the die; and

FIG. 4 is a cross section of the die and heat sink as part of a packaged device.

### DETAILED DESCRIPTION

A die has a gold coating, and a substrate has a gold layer and a palladium layer. The gold layers of the die and substrate are pressed together and heated to form a eutectic bond in which an intermetallic precipitate comprising gold, palladium, and silicon is formed in the eutectic bond region between the die and the substrate. The eutectic bond is effective for providing the needed attachment and heat conductivity. The thickness of the gold layer on the metal layer is much less than that previously required because of the palladium layer. The combined thickness of the palladium layer and the gold layer on the substrate is much less than the thickness of

2

the gold layer previously required. Gold may be only required on one of the die or substrate prior to forming the eutectic bond. This is better understood by reference to the drawings and the following specification.

5 The semiconductor substrate of the die described herein can be any semiconductor material or combinations of materials, silicon germanium, silicon-on-insulator (SOI), silicon, monocrystalline silicon, polysilicon, the like, and combinations of the above, that contain silicon.

10 Shown in FIG. 1 is a die structure 10 and a substrate 12 in preparation for a die bonding operation. Die structure 10 comprises a die 14 and a gold layer 16 attached to a backside of die 14. At the interface of the backside of die 14 and gold layer 16, the backside comprises silicon. Substrate 12 has a primary portion 18, a barrier layer 20 on primary portion 18, a palladium layer 22 on barrier layer 20, and a gold layer 24 on palladium layer 22. Primary portion 18 is sufficiently strong to provide physical support for die 14 and be a metal heat sink comprised of copper, CuMoCu, Cu(CuMo)Cu, aluminum, or silicon carbide. Other materials may be used as well. One example is that primary portion 18 may be ceramic. Barrier layer 20 may comprise cobalt and nickel and be about 1-10 microns in thickness. Palladium layer may be 0.03 to 0.5 micron in thickness. Gold layer 24 may be about 0.03 to 0.4 micron in thickness. Gold layer 16 may be about 1.2 microns in thickness which is a common thickness for a gold layer on the backside of a die. Gold layer 24, which is beneficial but may not be necessary, is of a much less thickness than is commonly used for being on a substrate on to which a die will be bonded. As shown in FIG. 1, gold layer 16 is facing gold layer 24 in preparation for a bonding operation which may be a eutectic bonding operation in which gold layers 16 and 24 will be pressed together and heated and in which there is some small movement, called scrubbing, between gold layers 16 and 24.

Shown in FIG. 2 are die 14 and primary portion 18 after the eutectic bonding operation in which gold layers 16 and 24 were brought together with pressure, scrubbing, and heat to form a die attach layer 26. Die attach layer 26 is a combination of gold layers, a small portion of silicon from die 14, gold layer 16, gold layer 24, palladium layer 22, and a portion of barrier layer 20. Die attach layer 26 provides attachment to die 14 and to barrier layer 20. Barrier layer 20 adheres well to primary portion 18. Die attach layer 26 also conducts heat between die 14 and barrier layer 20.

Shown in FIG. 3 is a more detailed view of die attach layer 26. Die attach layer 26 includes a thin nickel cobalt silicide layer 32 of less than 0.2 micron at the interface with barrier layer 20. A material other nickel cobalt silicide may be used. One example is nickel silicide. Nickel cobalt silicide layer 32 is likely not to be continuous and not to be of uniform thickness. Die attach layer 26 includes a gold interface layer 30 that may be about 0.1 to 10 microns thick and that comprises gold and precipitates in the gold. The predominate precipitate is combination of palladium (Pd), gold (Au), silicon (Si), cobalt (Co), nickel (Ni) and may be expressed as PdAuSiCoNi. Examples of the PdAuSiCoNi precipitates are PdAuSiCoNi precipitate 34, PdAuSiCoNi precipitate 35, PdAuSiCoNi precipitate 36, and PdAuSiCoNi precipitate 37. PdAuSiCoNi precipitates 34-37 are spherical or elliptical and vary in size but can be 0.1 micron in diameter. May more PdAuSiCoNi would be present than shown in FIG. 3. Another precipitate is nickel cobalt silicide which are shown in FIG. 3 as silicide precipitates 38 and 39 and which are formed as strings that can be 0.2 micron in length. Another likely precipitate is silicon. This is shown in FIG. 3 as silicon precipitates 40, 41, and 42. The silicon precipitates may not actually occur. When

they do, they are much smaller than the PdAuSiCoNi and silicide precipitates. The silicon precipitates and the silicide precipitates total less than 10 percent of the volume of gold interface layer 30. On the other hand, PdAuSiCoNi precipitates form a significant percentage of the volume of gold interface layer 30. The percentage can easily be 5 to 70 percent. It is believed that all of the gold and palladium with some silicon become liquid at the die attach temperature and then precipitates out as an intermetallic and gold layer.

The eutectic process is performed by joining substrate 12 and die structure at a temperature that is preferably between 390 to 430 degrees Celsius but could be at other temperatures such as between 370 degrees Celsius and 450 degrees Celsius. A force of about 30 gram force is applied between die structure 10 and substrate 12. This is applied for about one minute. The scrubbing is performed with an amplitude of about 10 microns at a frequency of about 100 hertz. Other forces and scrubbing parameters may be used instead.

The prior art approach of using two gold layers of multi-micron thickness without palladium also formed a thin silicide layer like silicide layer 32 with silicide and perhaps silicon precipitates. The precipitates of this prior art approach were of minimal percentage of the resulting gold interface layer, less than 30 percent by volume.

The affect of die attach layer 26 is to provide a degree of attachment and heat conduction that is comparable to that of the described prior art approach but with reduced cost. Palladium is currently about  $\frac{1}{3}$  the cost of gold on a weight basis but gold has about twice the density. Thus, a given thickness of palladium will be about  $\frac{1}{6}$  the cost of the same thickness of gold. Further the thickness of the palladium layer as described is only about 0.03 to 0.5 micron whereas the described prior art approach uses about 1.5 to 2.5 microns of gold on the substrate side while retaining the same gold thickness on the die side. The surface area on the substrate that is coated with gold is much greater than the area of the backside of the die. This ratio of areas can easily be 30 to 1. Thus a reduction of thickness of the gold on the substrate side saves significantly more gold than the same reduction in thickness of gold on the die side. In fact, gold on the back side of the die can be increased to 2.5 microns if needed. The reason why palladium and the consequent formation of PdAuSiCoNi precipitates results in significantly reducing the need of gold, especially on the substrate side, while obtaining the desired adhesion and heat conduction is not fully understood, but it is believed the PdAuSiCoNi precipitates provide for a stronger bond for a given thickness of a resulting gold interface layer such as gold interface layer 30. Also that the cobalt and nickel may not be required in the precipitate. Their presence occurs because of the presence of the barrier layer, but the effectiveness of gold interface layer 30 is not believed to require cobalt or nickel in the palladium-containing precipitates. Thus, if barrier layer 20 can be found to not be required, then it is believed to not be required for the gold interface layer. Thus altering the palladium-containing precipitates of gold interface layer 30 by removing the cobalt and nickel would result in an effective gold interface layer.

An option can be to put all of the gold on the die side so that substrate 12 will not have a gold layer but will have the palladium layer exposed and be the surface that comes in contact with the die in the bonding process. This may simplify the process a little by not requiring the step of plating gold on the substrate. Also any reduction in gold on the substrate side potentially saves more gold because of the comparatively large area of the substrate. It's also possible to put all of the gold on the substrate side, but this is putting gold on the side with the larger area so that the cost savings is reduced.

Shown in FIG. 4 is a packaged device 44 comprising die 14, a die 46 and a die 48 attached to primary portion 18 of substrate 12 through die attach layers 26, 66, and 68, respectively. Packaged device 44 further comprises leads 62 and 64, a cap 60, and wire bonds 50, 52, 54, and 56. Leads 62 and 64 extend laterally and have underlying insulating layers 63 and 65 respectively, for the case where primary portion 18 is conductive. A cap 60 covers die 14, 46, and 48 and is on leads 62 and 64 so that each of leads 62 and 64 have an inner portion available for wire bonding and an outer portion for connecting to a system. Wire bond 50 is connected between the inner portion of lead 62 and die 46. Wire bond 52 is connected between die 46 and die 48. Wire bond 54 is connected between die 48 and die 14. Wire bond 56 is connected between die 14 and the inner portion of lead 64. Other die could also be present. Additional wire bonds among the die and between the die and other leads are also present. Die attach layers 26, 66, and 68 can be formed at the same time. Thus multiple die can be formed on the same substrate and in the same package using the described technique of forming die attach layers such as die attach layer 26. Passive elements made with ceramic, silicon, and gallium arsenide can also be included with a gold/tin or epoxy attach. This also shows the much greater area of a substrate compared to the backside of the die. For a gold plating process, it is also likely that all sides of the substrate will be coated with gold. Thus any savings in thickness can be very significant.

By now it should be appreciated that there has been a method for forming a semiconductor device. The method includes providing a silicon-containing die having a first surface. The method further includes providing a heat sink having a palladium layer over a first surface of the heat sink, wherein a first gold layer is located over one of a group consisting of the palladium layer and the first surface of the silicon-containing die. The method further includes bonding the silicon-containing die to the heat sink. The bonding includes joining the silicon-containing die and the heat sink such that the first gold layer and the palladium layer are between the first surface of the silicon-containing die and the first surface of the heat sink. The bonding further includes heating the first gold layer and the palladium layer to form a die attach layer between the first surface of the silicon-containing die and the first surface of the heat sink, the die attach layer comprising a gold interface layer having a plurality of intermetallic precipitates, each of the plurality of intermetallic precipitates comprising palladium, gold, and silicon. The method may have a further characterization by which the step of providing the silicon-containing die is further characterized in that the first gold layer is located over the first surface of the silicon-containing die. The method may have a further characterization by which wherein the step of providing the heat sink is further characterized in that the heat sink has a second gold layer over the palladium layer, and wherein the step of joining is further characterized in that the first gold layer, the second gold layer, and the palladium layer are between the first surface of the silicon-containing die and the first surface of the heat sink, and wherein the step of heating is further characterized in that the silicon from the silicon-containing die, the first gold layer, the second gold layer, and the palladium layer are heated to form the die attach layer. The method may have a further characterization by which the step of providing the heat sink is further characterized in that the heat sink has a barrier layer over the first surface of the heat sink, the palladium layer being over the barrier layer, wherein the step of joining is further characterized in that the first gold layer, the second gold layer, the palladium layer, and the barrier layer are between the first surface of the silicon-con-

5

taining die and the first surface of the heat sink, and wherein the step of heating is further characterized in that silicon from the silicon-containing die, the first gold layer, the second gold layer, the palladium layer, and the barrier layer are heated to form the die attach layer. The method may have a further characterization by which the step of providing the heat sink is further characterized in that the heat sink has a barrier layer over the first surface of the heat sink, wherein the palladium layer is over the barrier layer. The method may have a further characterization by which the step of providing the heat sink is further characterized in that the barrier layer comprises nickel, and wherein the step of heating is further characterized in that the first gold layer, the palladium layer, and the barrier layer are heated to form the die attach layer, wherein a portion of the barrier layer forms a nickel-containing silicide layer, wherein the die attach layer comprises the nickel-containing silicide layer, and the nickel-containing silicide layer is between the gold interface layer and the barrier layer. The method may have a further characterization by which the step of bonding is further characterized in that each of the plurality of intermetallic precipitates further comprises nickel. The method may have a further characterization by which the step of bonding is further characterized in that the die attach layer has a thickness in a range of 0.1 to 10 microns. The method may have a further characterization by which the step of bonding is further characterized in that, after the step of joining, the first gold layer is in contact with a silicon portion of the silicon-containing die.

Also described is a method for forming a semiconductor device. The method includes providing a silicon-containing die having a first gold layer over a first surface of the silicon-containing die. The method further includes providing a heat sink having a palladium layer over a first surface of the heat sink, and a second gold layer over the palladium layer. The method further includes bonding the silicon-containing die to the heat sink, wherein the bonding comprises bringing the first gold layer into contact with the second gold layer and heating the first gold layer, the second gold layer, and the palladium layer to form a die attach layer between the first surface of the silicon-containing die and the first surface of the heat sink, the die attach layer comprising a gold interface layer having a plurality of intermetallic precipitates, each of the plurality of intermetallic precipitates comprising palladium, gold, and silicon. The method may have a further characterization by which the step of providing the heat sink is further characterized in that the heat sink has a barrier layer over the first surface of the heat sink, wherein the palladium layer is over the barrier layer. The method may have a further characterization by which step of providing the heat sink is further characterized in that the barrier layer comprises nickel, and wherein the step of heating is further characterized in that the first gold layer, the palladium layer, and the barrier layer are heated to form the die attach layer, wherein a portion of the barrier layer forms a nickel-containing silicide layer, wherein the die attach layer comprises the nickel-containing silicide layer, and the nickel-containing silicide layer is between the gold interface layer and the barrier layer. The method may have a further characterization by which the step of bonding is further characterized in that each of the plurality of intermetallic precipitates further comprises nickel. The method may have a further characterization by which the step of providing the heat sink is further characterized in that the barrier layer comprises nickel cobalt, and wherein the step of bonding is further characterized in that each of the plurality of intermetallic precipitates further comprises nickel and cobalt. The method may have a further characterization by which the step of bonding is further characterized in that the die attach

6

layer has a thickness in a range of 0.1 to 10 microns. The method may have a further characterization by which the step of providing the silicon-containing die is further characterized in that the first gold layer has a thickness in a range of 1.2 to 2.0 microns. The method may have a further characterization by which the step of providing the heat sink is further characterized in that the second gold layer has a thickness in a range of 0.03 to 0.4 micron, and the palladium layer has a thickness in a range of 0.03 to 0.5 micron. The method may further comprise packaging the silicon-containing die to form a packaged semiconductor device, wherein the packaging comprises forming an electrical connection between a second surface of the silicon-containing die, opposite the first surface of the silicon-containing die, and an external lead of the packaged semiconductor device.

Described also is a semiconductor device. The semiconductor device includes a heat sink. The semiconductor device further includes a silicon-containing die attached to the heat sink with a die attach layer, wherein the die attach layer comprises a gold interface layer having a plurality of intermetallic precipitates, each of the plurality of intermetallic precipitates comprising palladium, gold, and silicon. The semiconductor device may further include a nickel-containing barrier layer between the die attach layer and the heat sink, and wherein the die attach layer comprises a nickel-containing silicide layer between the gold interface layer and the nickel-containing barrier layer, and wherein each of the plurality of intermetallic precipitates comprises palladium, gold, silicon, and nickel.

Moreover, the terms “front,” “back,” “top,” “bottom,” “over,” “under” and the like in the description and in the claims, if any, are used for descriptive purposes and not necessarily for describing permanent relative positions. It is understood that the terms so used are interchangeable under appropriate circumstances such that the embodiments of the invention described herein are, for example, capable of operation in other orientations than those illustrated or otherwise described herein.

Although the invention is described herein with reference to specific embodiments, various modifications and changes can be made without departing from the scope of the present invention as set forth in the claims below. For example, other packing approaches may be used such as an encapsulation technique that does not have a cavity. The barrier layer may be of another material and may not even be necessary. Accordingly, the specification and figures are to be regarded in an illustrative rather than a restrictive sense, and all such modifications are intended to be included within the scope of the present invention. Any benefits, advantages, or solutions to problems that are described herein with regard to specific embodiments are not intended to be construed as a critical, required, or essential feature or element of any or all the claims.

Furthermore, the terms “a” or “an,” as used herein, are defined as one or more than one. Also, the use of introductory phrases such as “at least one” and “one or more” in the claims should not be construed to imply that the introduction of another claim element by the indefinite articles “a” or “an” limits any particular claim containing such introduced claim element to inventions containing only one such element, even when the same claim includes the introductory phrases “one or more” or “at least one” and indefinite articles such as “a” or “an.” The same holds true for the use of definite articles.

Unless stated otherwise, terms such as “first” and “second” are used to arbitrarily distinguish between the elements such terms describe. Thus, these terms are not necessarily intended to indicate temporal or other prioritization of such elements.

What is claimed is:

1. A method for forming a semiconductor device that includes a die and a substrate, the method comprising:  
forming a barrier layer over a first surface of a portion of the substrate;

forming a palladium layer over the barrier layer;

forming a first gold layer over a first surface of the die; and  
bonding the die and the substrate by

pressing together the die and the substrate such that the first gold layer and the palladium layer are between the die and the substrate, and

heating the first gold layer and the palladium layer to form a die attach layer between the die and the substrate, the die attach layer comprising a gold interface layer that includes gold and a plurality of first precipitates in the gold, wherein each of the first precipitates comprises a combination of nickel, cobalt, palladium, gold, and silicon.

2. The method of forming a semiconductor device according to claim 1, wherein the barrier layer comprises cobalt and nickel.

3. The method of forming a semiconductor device according to claim 1, wherein forming the barrier layer comprises forming the barrier layer to have a thickness in a range of 1 micron to 10 microns.

4. The method of forming a semiconductor device according to claim 1, wherein forming the palladium layer comprises forming the palladium layer to have a thickness in a range of 0.03 micron to 0.5 micron.

5. The method for forming a semiconductor device according to claim 1, wherein forming the first gold layer comprises forming the first gold layer to have a thickness in a range of 1.2 microns to 2.0 microns.

6. The method for forming a semiconductor device according to claim 1, wherein forming the first gold layer comprises forming the first gold layer to have a thickness of up to 2.5 microns.

7. The method of forming a semiconductor device according to claim 1, further comprising:

forming a second gold layer over the palladium layer prior to bonding the die and the substrate.

8. The method for forming a semiconductor device according to claim 7, wherein forming the second gold layer comprises forming the second gold layer to have a thickness in a range of at least 0.03 microns.

9. The method for forming a semiconductor device according to claim 1, wherein heating the first gold layer and the palladium layer comprises heating the substrate and the die to a temperature of 430 degrees Celsius or less.

10. The method for forming a semiconductor device according to claim 1, wherein pressing together the die and the substrate comprises applying a force between the die and the substrate.

11. The method for forming a semiconductor device according to claim 1, wherein bonding the die and the substrate further comprises scrubbing together the die and the substrate.

12. The method for forming a semiconductor device according to claim 1, wherein the step of bonding is further characterized in that the die attach layer has a thickness in a range of 0.1 microns to 10 microns.

13. The method for forming a semiconductor device according to claim 1, wherein the step of bonding is further characterized in that, after the step of bonding, the first gold layer is in contact with a silicon portion of the die.

14. The method for forming a semiconductor device according to claim 1, further comprising:

coupling a plurality of leads to the substrate; and

forming electrical connections between the die and the plurality of leads.

15. The method for forming a semiconductor device according to claim 14, further comprising:

coupling insulating layers between the primary portion of the substrate and the leads.

16. A method for forming a semiconductor device that includes a die and a substrate, the method comprising:

pressing together the die and the substrate such that a first gold layer and one or more additional material layers are between the die and the substrate; and

performing a bonding operation to form a die attach layer between the die and the substrate, the die attach layer comprising a gold interface layer that includes gold and a plurality of first precipitates in the gold, wherein each of the first precipitates comprises a combination of nickel, cobalt, palladium, gold, and silicon.

17. The method for forming a semiconductor device according to claim 16, further comprising the steps, performed before pressing together the die and the substrate, of:  
forming a barrier layer comprising cobalt and nickel over a first surface of a portion of the substrate;

forming a palladium layer over the barrier layer; and

forming the first gold layer over a first surface of the die.

18. The method for forming a semiconductor device according to claim 17, wherein forming the first gold layer comprises forming the first gold layer to have a thickness up to 2.5 microns.

19. The method of forming a semiconductor device according to claim 17, further comprising:

forming a second gold layer over the palladium layer prior to pressing together the die and the substrate.

20. The method for forming a semiconductor device according to claim 19, wherein forming the second gold layer comprises forming the second gold layer to have a thickness of at least 0.03 microns.
